

The first of these is the fact that the system is not in a steady state. The number of particles in the system is increasing at a constant rate, and this leads to a corresponding increase in the number of collisions. The second is that the system is not in thermal equilibrium. The temperature of the system is increasing at a constant rate, and this leads to a corresponding increase in the average kinetic energy of the particles. The third is that the system is not in a state of maximum entropy. The entropy of the system is increasing at a constant rate, and this leads to a corresponding increase in the number of microstates.
